Introduction to UML and Class Diagrams

UML

- Unified Modelling Language (UML)
- UML is a graphical modelling Language
  - **graphical** --- UML documents are diagrams
  - **modelling** --- UML is for describing systems
  - **systems** --- may be software systems or domains (e.g. business systems), etc.
- It is **semi-formal**
  - The UML definition tries to give a reasonably well defined meaning to each construct

Three Ways of Using UML

- UML as sketch
  - Used to sketch out **some** aspects of the system
  - Create diagrams only for important classes and interactions
- UML as blueprint
  - Complete design for the whole system
  - Interfaces for all subsystems specified (but not implementation!)
- UML as programming language
  - Diagrams compiled directly to executable code!
  - Neat idea, but not mainstream
- We will utilize UML as sketch in this course

Classes

- Classes are specifications for objects
- Parts of a class:
  - Name
  - Set of *attributes* (*aka data members or fields*)
  - Set of *operations*
    - Constructors: initialize the object state
    - Accessors: report on the object state
    - Mutators: alter the object state
    - Destructors: clean up (finalizers in C#, rarely needed)

Attributes

Operations

```
class Point
{
    private double x, y;

    public Point(double x, double y)
    {
        this.x = x;
        this.y = y;
    }

    double GetX() { return x; }
    void SetX(double inX) { x = inX; }
    // ...
}
```

UML Representation of a Class

```
class Student
{
    private long studNum;
    private string name;

    public Student(long sn, String nm)
    {
        studNum = sn;
        name = nm;
    }

    public String GetName() {
        return name;
    }
    public long GetNumber() {
        return studNum;
    }
}
```

Classes in UML

UML can be used for many purposes.

- In *software design* UML classes usually correspond to classes in the code.
- But in *domain analysis* UML classes are typically classes of real objects (e.g. real students) rather than their software representations.

Usage of (Software) Classes in C#

A class `C` can be used in 3 ways:

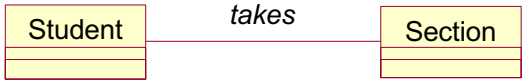
- **Instantiation**. You can use `C` to create new objects.
  - Example: `new C()`
- **Extension**. You can use `C` as the basis for implementing other classes
  - Example: `class D : C { … }`
- **Type**. You can use `C` as a type
  - Examples: `C Method( C p ) { C q ;… }`

Relationships Between Classes

- Association
- Aggregation
- Composition
- Dependence
- Generalization

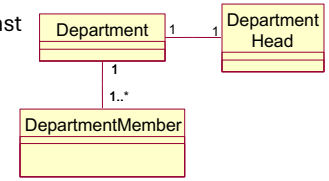
Association Relationships

- Association is a general-purpose relationship between classes.
- Associations may be named.
- Associations are often implemented with pointers (C++) or reference variables (C#)



Multiplicity Constraints

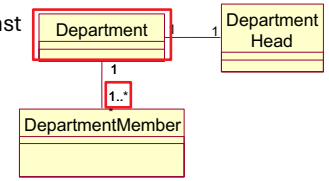
- Each Department is associated with one DepartmentHead and at least one DepartmentMember
- Each DepartmentHead and DepartmentMember is associated with one Department
- No constraint means multiplicity is unspecified



Multiplicity Constraints

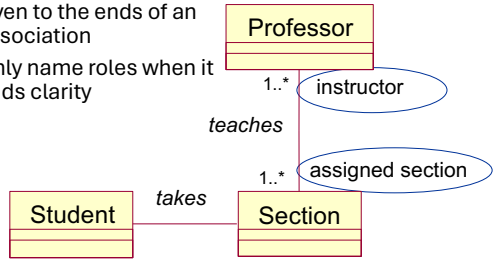
NOTE: The multiplicity for any class association is located at the far end of the line

- Each Department is associated with one DepartmentHead and at least one DepartmentMember
- Each DepartmentHead and DepartmentMember is associated with one Department
- No constraint means multiplicity is unspecified



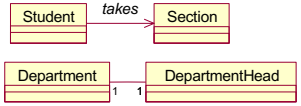
Role names

- Role names may be given to the ends of an association
- Only name roles when it adds clarity



Navigability

- An arrow-head indicates the direction of navigability.
- E.g. Given a student object, we can easily find all Sections the student is taking.
- No arrow-head: means navigability in both directions.



Implementing Navigable Associations (1)

Usually implemented with data members

```
class Student
{
    private List<Section> sections;
    // ...
}
```

Implementing Navigable Associations (2)

If bi-directional, then each objects of each class should be reachable from the other

```
class DepartmentHead
{
    private Department dept;
    // ...
}

class Department
{
    private DepartmentHead deptHead;
    // ...
}
```

Implementing Associations Indirectly

- An association between objects might also be stored outside of the objects

```
class Department
{
    private static Dictionary<Department, DepartmentHead> heads =
                new Dictionary<Department, DepartmentHead>();

    DepartmentHead GetHead()
    {
        return heads[this];
    }
    // ...
}
```

Aggregation

- Aggregation is a special case of association.
- It is used when there is a "whole-part" relationship between objects.
- Denoted with an unfilled diamond at the "whole" end
- eg. A Club is an aggregation of Persons (the members of the club)

Composition

- Composition is a special case of aggregation
- Composition is appropriate when
  - each part is a part of one whole
  - the lifetime of the whole and the part are the same
- Denoted by a solid diamond at the "whole" end
- eg.

  A Polygon is composed of 3 or more Points

Composition vs. Aggregation

- The difference between composition and aggregation is lifetime
- For example, if whenever the points that compose it are destroyed, the polygon is destroyed (and vice versa) then we have composition

- But maybe this is not what what we want. If we allow the points to exist independently of the polygon, then we can also use them to define other shapes

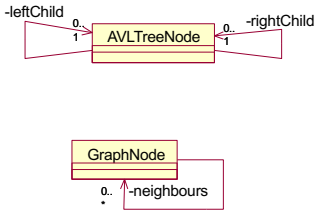
Note: Class Diagrams Show Class Relationships, Not Object Relationships

- Consider again this example:

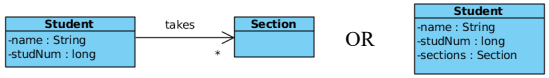
- We're not saying that the same points (i.e. instances of Point) are necessarily shared by Polygons and Circles, but they could be

Recursive associations

- Associations may relate a class to itself.
- The objects of the class may or may not be associated with themselves.



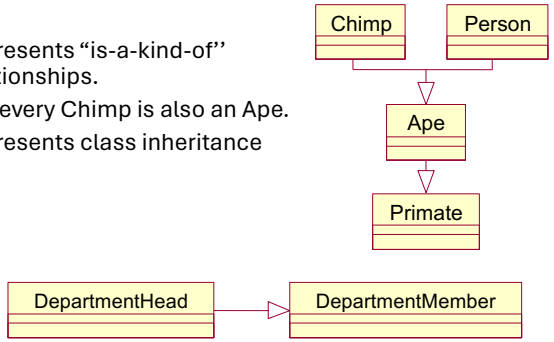
Associations vs. attributes



- Both are usually implemented by variables within the class
  - Fields or properties (C#), data members (C++).
- Use association for references that point to classes or interfaces.
  - Or use aggregation or composition if appropriate
- Use attributes for primitive types such as int, boolean, char

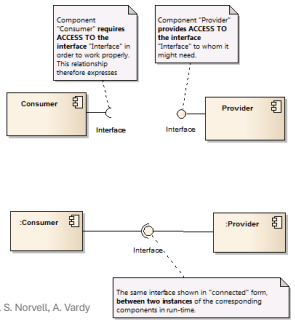
Generalization/Specialization

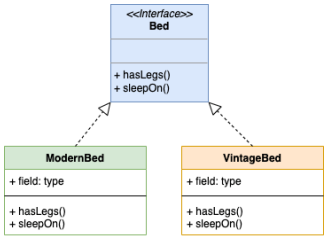
- Represents “is-a-kind-of” relationships.
- E.g. every Chimp is also an Ape.
- Represents class inheritance



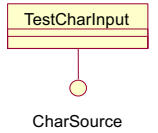
Interfaces

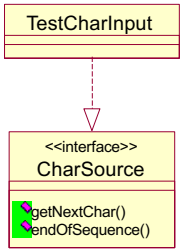
- Interfaces are classes with no associated implementation.
- Two styles:
  - "Lollipop" (shown on left)
  - "Traditoinal (shown on right)





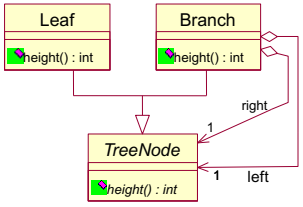
- Classes "specialize" classes, but "realize" interfaces
- The two style choices are shown





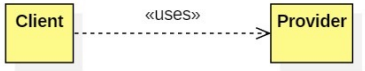
Abstract in Visual Paradigm (VP)

- In VP classes are made abstract with a checkbox in the specification.
- Likewise for operations (class must be abstract first).
- Italics indicate abstractness



Dependency

- Dependency is the weakest form of relationship
- A class C depends on class D if the implementation or interface of C even mentions D



- Dependencies are important to note because unneeded dependence makes components...
  - harder to reuse in another context
  - harder to isolate for testing
- It is better to depend on an interface than on a class.
- More on this later...
